Fluid Phase Space Optimization

Treating electron correlation as an informational fluid to bypass combinatorial walls.

The core solver reformulates electronic self-consistency as a kinetic transport process. By propagating the density matrix as a phase-space distribution and relaxing it via a Bhatnagar-Gross-Krook (BGK) collision operator, we replace static eigenvalue diagonalization with the entropic equilibration of an informational fluid. This naturally resolves topological singularities without relying on exponential $O(N!)$ combinatorial scaling.
